

How can large entropy be produced so early at RHIC?

E. Shuryak
(Stony Brook)

- Hydro description works extremely well,
[including rather peripheral ($B \sim 10 \text{ fm}$) ellipticity
and large $P_{\perp} \sim 2 \div 3 \text{ GeV} \rightarrow$ nothing like that at SPS]

! EOS which fits best agrees with lattice!

- Estimates of early parton density (Gyulassy, Wang)
from: (i) "jet quenching" $\rightarrow \pi^0(P_{\perp} > 3 \text{ GeV, central})$
(ii) $v_2(P_{\perp} > 2 \text{ GeV})$

give

$$\frac{dN_q}{dy} \sim 1000$$

Much more than
pQCD, HIJING...

← Close to observed
or "Slate" →

$$\frac{dN_{\pi}}{dy} \sim 1000$$

"Slate"

Supports nearly adiabatic expansion!

Like in Big Bang

- New non-perturbative mechanism of parton-parton collisions, the so called instanton/sphaleron mechanism may produce it!

Developed recently for explanation
of soft Pomeron

without connection to heavy ions...

How good is hydro? (U.S. "few scattering model")

At RHIC deviation from hydro
 only for very peripheral, $N_p / N_p^{max} < 0.1$

at SPS start
 at ~ 0.6

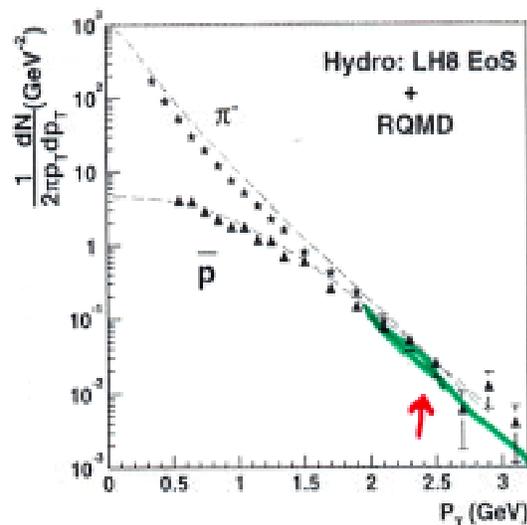

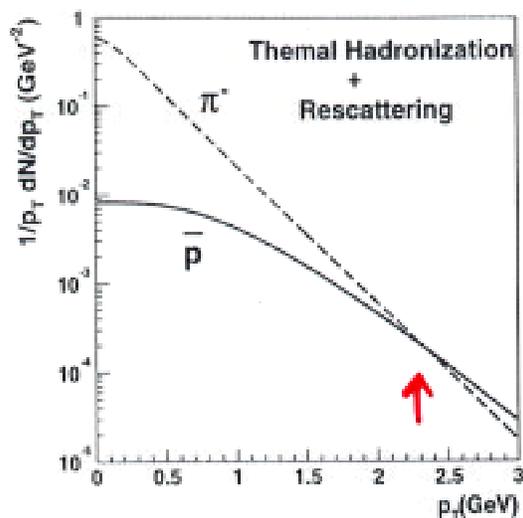

Where is the transparent region?

Heiselberg...

Hydro:
 $v_2 \sim \epsilon \sim (N_p - N_p^{max})$
 small density limit:
 $v_2 \sim N_p$
 not seen

Figure 3: v_2 versus impact parameter b , described experimentally by the number of participant nucleons, for RHIC STAR and SPS NA49 experiments. Both are compared to our results, for EoS LH8.

Phenix
π⁰

- Radial flow increases p, \bar{p} slopes as compared to π ones \rightarrow crossing

$\Rightarrow \bar{p}/\pi^-$ ratio exceed 1 for $p_T > 2$ GeV (never seen before...)

[fig. a demonstrate it with simple Blast model $v_{\perp} \approx 0.6$]

[fig. B is H2H model (absolutely normalized predictions) vs PHENIX data]

- At $p_{\perp} \rightarrow \infty$ slopes become the same "blue shifted"
 $"T" = T \sqrt{\frac{1+v_{\perp}}{1-v_{\perp}}} \approx 2T$ there "thermal ratio" $\frac{\bar{p}}{\pi^-} \rightarrow 2$ (spins)

- Hard processes (jet or minijet fragment.) predict $\bar{p}/\pi^- \approx 0.1 \div 0.3 \ll 1$

(One more argument that jets are quenched!)

No power-like tail?

Jet quenching!

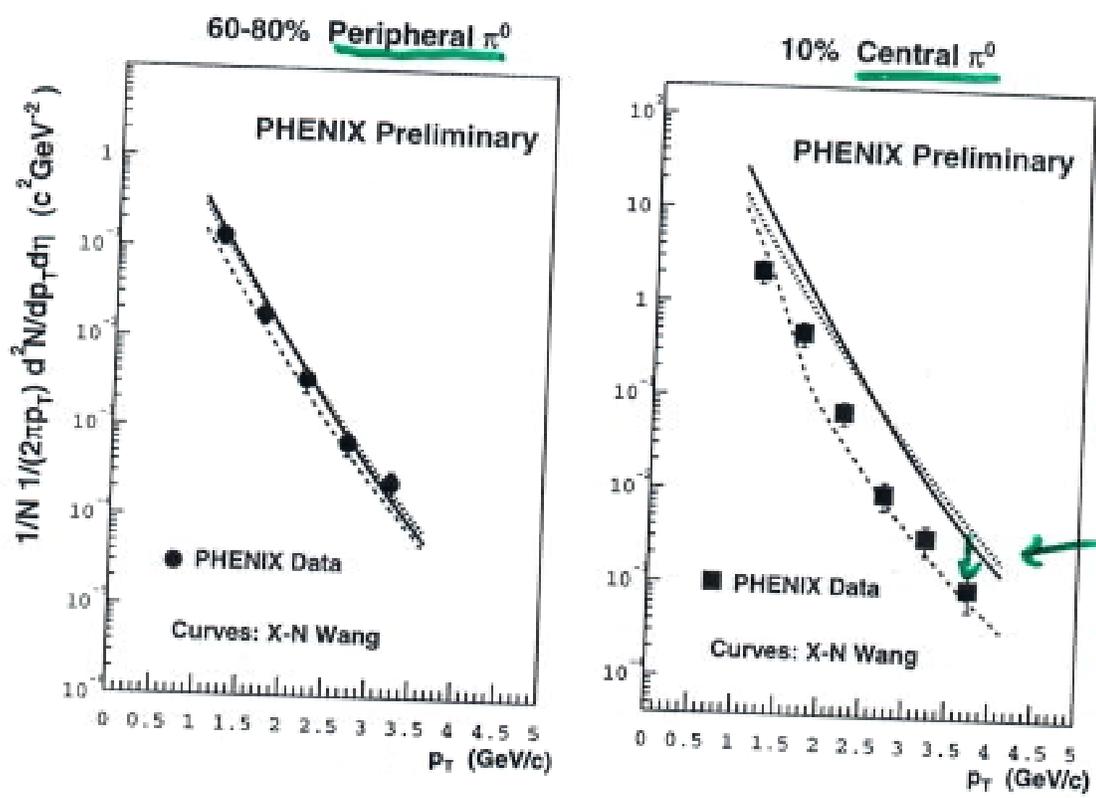

Figure 3. Comparison of PHENIX π^0 spectra to theoretical calculations under three scenarios and for two centralities. The points are the same as on Figure 1. The curves are calculations of X-N. Wang [1]. Solid lines are a pQCD calculation for pp scaled by the mean number of binary collisions. The dotted lines add shadowing and p_T broadening. The dashed lines add a $dE/dx = 0.25$ GeV/fm parton energy loss.

- Gyuassy et al: such suppression means $\Rightarrow \frac{L}{\lambda} \approx 3$ or $\frac{dN_g}{dy} \approx 1000$ (AuAu Central)
- Independent study of $v_2(p_T > 2 \text{ GeV})$ give the

Gyulassy, Vitev, Wang
nucl-th/0012092

Star data

favor
 $\frac{dN^8}{dy} \approx 1000 !!$

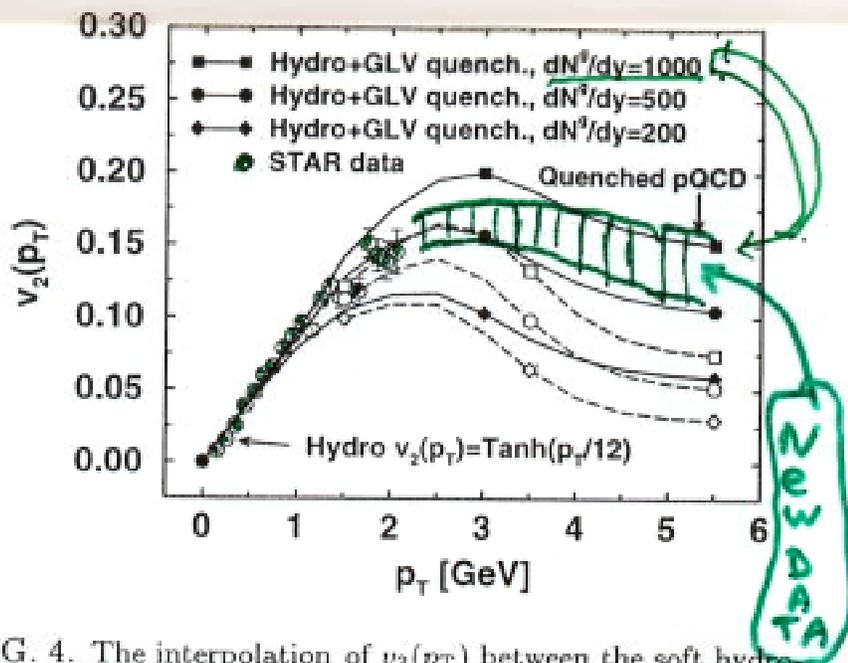

FIG. 4. The interpolation of $v_2(p_T)$ between the soft hydrodynamic [12] and hard pQCD regimes is shown for $b = 7$ fm. Solid (dashed) curves correspond to cylindrical (Wood-Saxon) geometries.

HIJING $\rightarrow 200$

(= pert. partonic reactions, $P_{\text{cutoff}}^2 \sim 20 \text{ GeV}^2$)

$\frac{dN^{\pi}}{dy} \approx 1000$ also

Conclusion

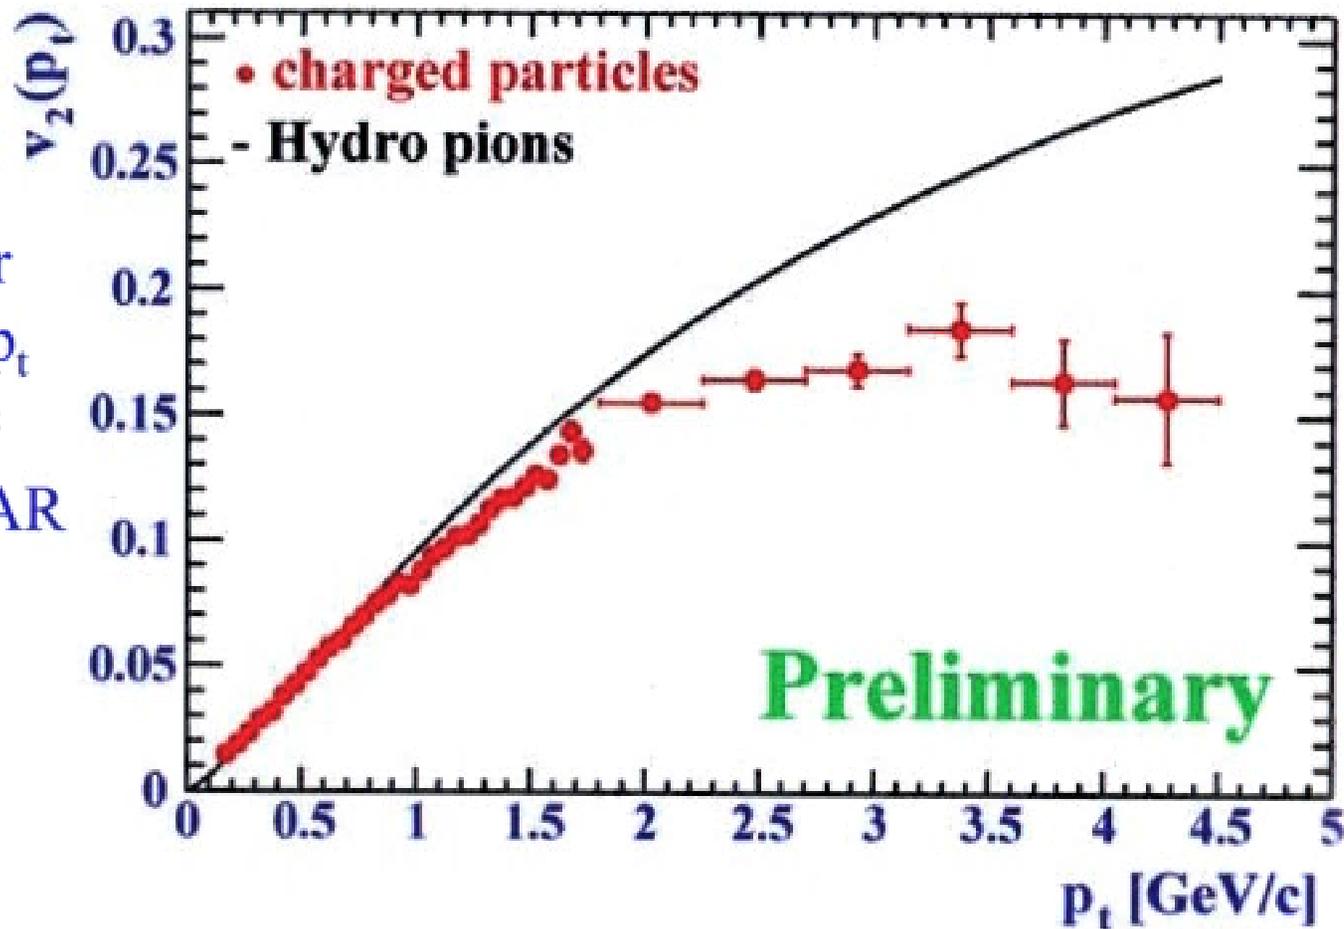

Like in the Big Bang,
in the little one
the whole entropy is there
even at earliest time we
can measure it!

Charged particle anisotropy

$$0 < p_t < 4.5 \text{ GeV}/c$$

STAR

Only statistical errors
Systematic error
10% - 20% for p_t
= 2 - 4.5 GeV/c
More in the STAR
high-pt talk
(James Dunlop,
PS2, this
afternoon)

- Why ^{does} the cross section grow?
 $\sigma \sim s^{(2-1)}$ Pomeron Regge pole \rightarrow not so high s

$$\sigma = \sigma_0 \left[1 + (\Delta(0) + \alpha' \ln s) \ln s + \dots \right]$$

The part which is constant with s
 $\sigma_0 \approx \frac{1}{9} \sigma_{NN} \Rightarrow r_0 = \frac{1}{3} r_{NN}$

$\Delta(0) \approx 0.08$ "Pomeron intercept"
 with $\alpha' \approx 0.15$ (Landschoff et al)
 $\alpha' \approx 0.25 \text{ GeV}^{-2}$ grows

- Why $\Delta(0)$ is so small?

$$\Delta(0) \approx \frac{\#}{O(1)} \left(\frac{3^2 \mu_0^4}{0.06} \right)$$

instanton diluteness
 current calculation
 (ES + I. P. et al, in progress)
 $\Delta(0) \approx 0.22$

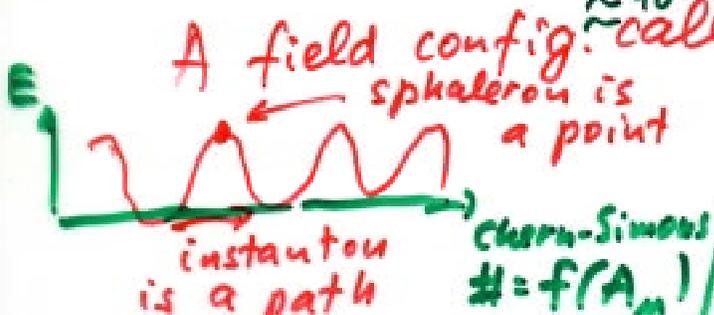

- Why α' is so ~~large~~ ^{small}?

$$\alpha' = \frac{1}{(26 \text{ GeV})^2} = (0.1 \text{ fm})^2$$

Because instantons are small!

current estimate $\alpha' \approx 0.5 \text{ GeV}^{-2}$

- What is produced in the process?

A field config. ^{~ to magnetic one} called the "sphaleron"

$$E_{\text{sph}} \approx \frac{3\pi^2}{g^2} \approx 25 \text{ GeV}$$

Klinkhammer
 Ntounou

Basically a set of glueballs (if zero color but not necessarily so...)

- No odderon! Instanton is $SU(2)$ object
 Odderon requires $a^3 c$ in $SU(3)$

Instanton/sphaleron mechanism

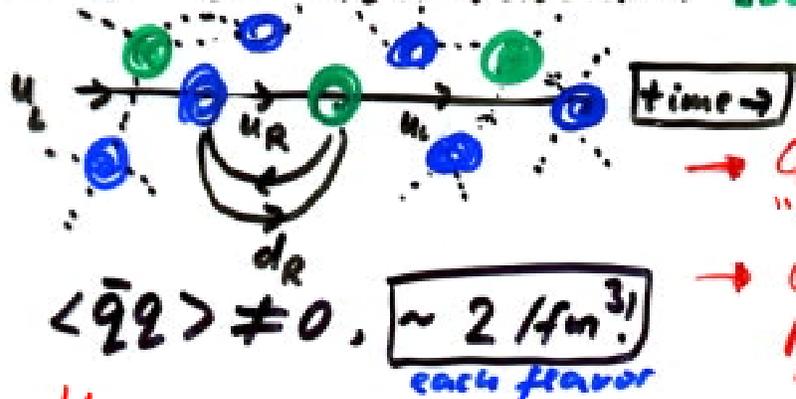

Sounds complicated, but the main physics is easy to understand...

Developed in electroweak theory in early 90's

Ringwald, McLerran, Zakharov, Khase, Diakonov

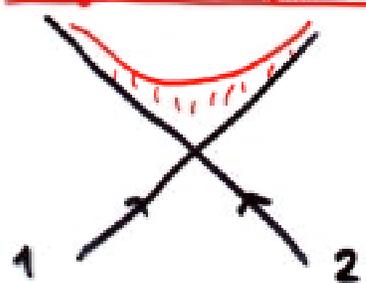

recently used for QCD Kharzeev, Kouchogov, Lenin Shuryak, Zahed...

The instanton vacuum ES82

- Quark gets a mass $\Rightarrow \sim 400MeV$ "constituent" quarks
- Quarks gets a sea, which is polarized in flavor and spin in opposite direction

High energy collision leads to sublimation of all this structure instantly

- Instantons (which are virtual objects used to describe tunneling) \Downarrow Sphalerons → Real Balls of magnetic glue which then explode
- Condensed quarks get real too!

Quantum mechanics of it is like this:

Vacuum

Collision, step 1

$\tau \sim 1/\sqrt{s}$

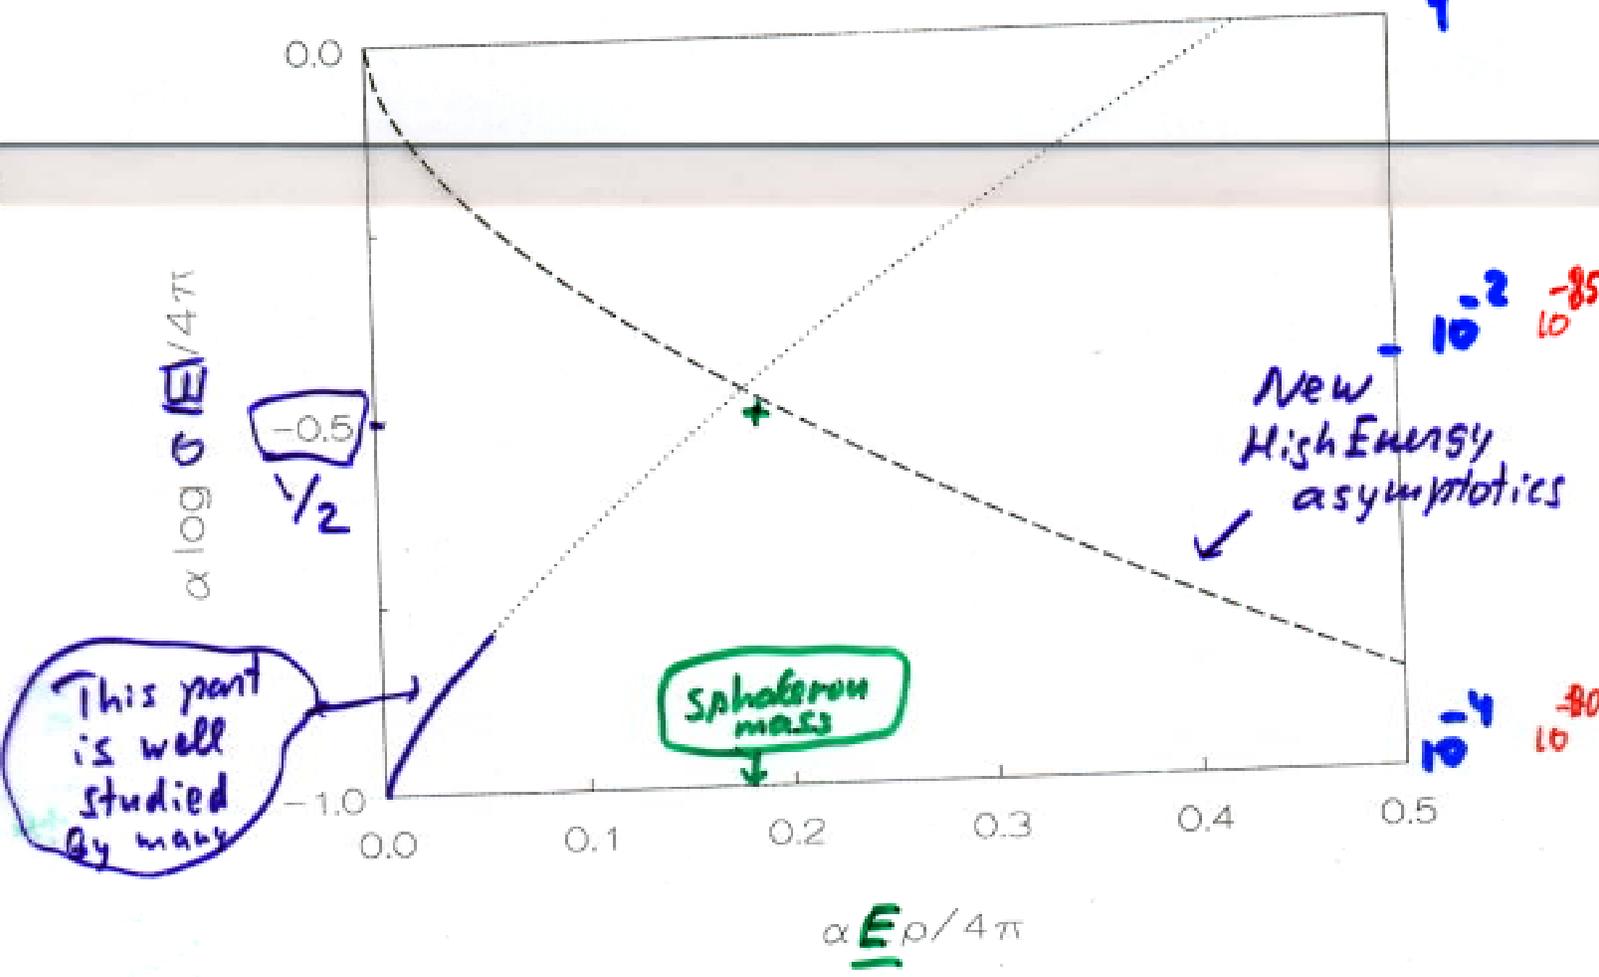

System is rapidly localized, wherever it is
The maximal cross section falls on sphaleron

Collision step 2

$\tau \sim g$

Sphalerons rolls downhill \Rightarrow gluons + quarks

QCD EW
1

D. Diakonov, V. Petrov → arXiv:hep-th/9307356 28 Jul 1993

$\int_{MDE} E$ is the gg (actually WW) energy

using a different path in the ~~space~~ space of all configurations...

Instanton/sphaleron mechanism @ RHIC?

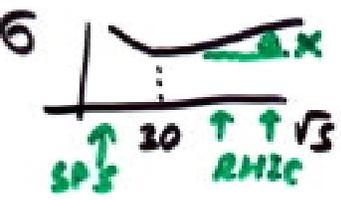

E.S. hep-ph/0101269
PLB, in press

● Partonic production mechanism $\frac{\# \text{ pions}}{\text{participant}} \rightarrow S$ Photos
B-dependence

$$M_{(S)} = \left(\frac{1-x}{2}\right) N_{\text{part}}(S) + x N_{\text{coll}}(S)$$

(Kharzeev, Nardi) $x = 0.05 \pm 0.03$ $\sqrt{s} = 56$ ← Part of PP which scales differently
 0.09 ± 0.03 130

● Can be identified with "growing part" of σ_{pp} ← (ES) leading to "prompt production" of some "objects"

$$\frac{d\sigma_{\text{objects}}}{dy} \Big|_{\text{parton-parton}} \sim \frac{\text{few}}{1000} \text{ fm}^2 \text{ (rare process)}$$

● And still, in central AuAu $\frac{dN_{\text{objects}}}{dy} \sim 100$ are produced

● What are these "objects"?

Minijets? $gg \rightarrow \text{"objects"} \rightarrow gg$

we discuss $p_T \sim 1-2 \text{ GeV}$ here! Cutoff unknown...

large angle

→ $\frac{dN_g}{dy} \sim 200$ (as HIJING predicted)

→ little rescattering, 40% no jet quenching

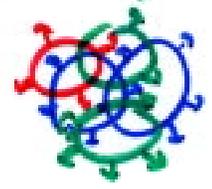

→ x early time picture

Sphalerons?

→ Unlike minijets, they are classically unstable and explode into spherical way into ~ 4 gluons

→ in QGP there are no condens. so $\bar{u}u, \bar{d}d$ (ES) jump out

same S, E_T but much more entropy...

"Ready to fall"

Sphaleron: mass and decay

• Magnetic object $\vec{B}(r)$

$$\vec{\nabla} \cdot \vec{B} = 0$$

$$\vec{\nabla} \times \vec{B} = 0$$

$B_i^a \sim \delta_{ij}^a$: hedgehog, like monopole
But no magnetic charge

$$A_i^a \sim \epsilon^{ajm} r^m f$$

(Klinkhamer, Manton) ¹⁹⁸⁴ in electroweak theory
 $M \sim 14 \text{ TeV}$, in $\lambda \rightarrow \infty$ limit Higgs decouples

$$M \approx \frac{30}{g^2 \rho} \sim 2.5 \text{ GeV in QCD, if } \rho = 1/3 \text{ fm}$$

• Decay

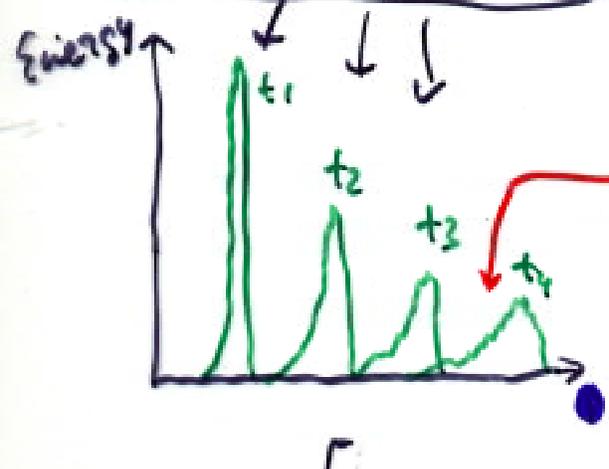

J. Zadozay, PL, 1992 for EW
G. Garter + ES \rightarrow in progress for QCD

Recall that in $A_0 = 0$ gauge

$$\vec{E} = \frac{\partial \vec{A}}{\partial t}$$
 ↑
 momentum
 (but \vec{E}^2 is gauge inv.)

spherical shells

ripples are not my chaky hand
But a trace of $e^{i\vec{k}\cdot\vec{r}}$
momentum $\vec{k} \rightarrow \text{const}$
 $r \rightarrow \infty$

$|c_k|^2$ occupation numbers $\rightarrow \text{const}$

EW sphalerons \rightarrow ~50 W+Z
about 200 GeV each

QCD sphalerons \rightarrow gluons
~500 GeV each

Puzzle:

Phenomenological Summary

Mini-jets vs Instanton-induced Clusters

In hh

→ Both can explain growth of $\sigma(s)$, multiplicity size

→ Mini-jets can be looked for as clusters in (θ, φ) statistically ...

→ Instanton-induced clusters, $M = 2.5 - 3$ GeV, isotropic $\Delta y \sim 1$, but $\Delta \varphi = 2\pi$

→ Mini-jets are expected to fragment as string fragm.
 → Standard $\lambda_{HBT} \approx 0.5$ and standard $\eta/\pi, \eta'/\pi, \kappa/\pi$

→ Enhanced η', η, κ , λ_{HBT} decreases, as observed!
 in pp at large multiplicity

In AuAu etc

→ Both can explain multiplicity growth, and why there appears new component at RHIC $\sim N_{coll}(B)$ (instead of $\sim N_{part}(B)$)

→ Mini-jets with a cutoff from pp fit (HIJING) lead to $\frac{dN}{dy} \sim 200$ mini-jets (central AuAu at RHIC)

It is not enough for collective effects and jet quenching
 Lower the cutoff? Higher order processes?

→ Instanton-induced reactions (into QGP, no hadrons) with similar cross section

leads to: much higher entropy!

and may solve quark production problem
